ABSTRACT

Ten sets of tires with nine different off-road tread patterns were tested on a paved surface using a towed, instrumented trailer to measure their cornering characteristics (wet and dry) and their braking performance (wet, full skid).

The data obtained and a method for rank ordering is presented.

INTRODUCTION

The adoption of radial ply tires by the military will present an ideal opportunity also to adopt a new tire tread pattern. Such a new tread pattern is desirable to make the radial tires easily identifiable in order to avoid, as much as possible, indiscriminate mixing of radial and bias tires, a recognized dangerous situation. A new pattern is also desirable to improve the traction characteristics of present military tires on wet pavements and to improve wear rates.

At present, there is no known theory or mathematical model, which will predict the performance of various tire tread patterns either on-or off-the highway. This program, therefore, investigated nine tire tread patterns which were selected by the U. S. Army Tank-Automotive Command (TACOM). This was the first step in a rather comprehensive program to develop a new military tread pattern which will improve on-road performance without degrading cross-country performance. Hopefully, this program will also obtain better insight into the part that tire tread patterns play in on- and off-road traction.

TEST PROGRAM

Two types of on-road tests were conducted: Measurements of tire cornering and tire braking forces. To conduct these tests at the loads desired, a special trailer was constructed (see Figure 1). This two-wheel trailer was provided with special linkages that would simultaneously yaw both tires in equal but opposite directions (see Figure 2). Both wheels were connected to an activator so that the yaw angle could be controlled remotely from the towing vehicle and the test wheel had an angular potentiometer mounted so that the angle could be measured and recorded. Mounted on the test wheel was a balance specially constructed

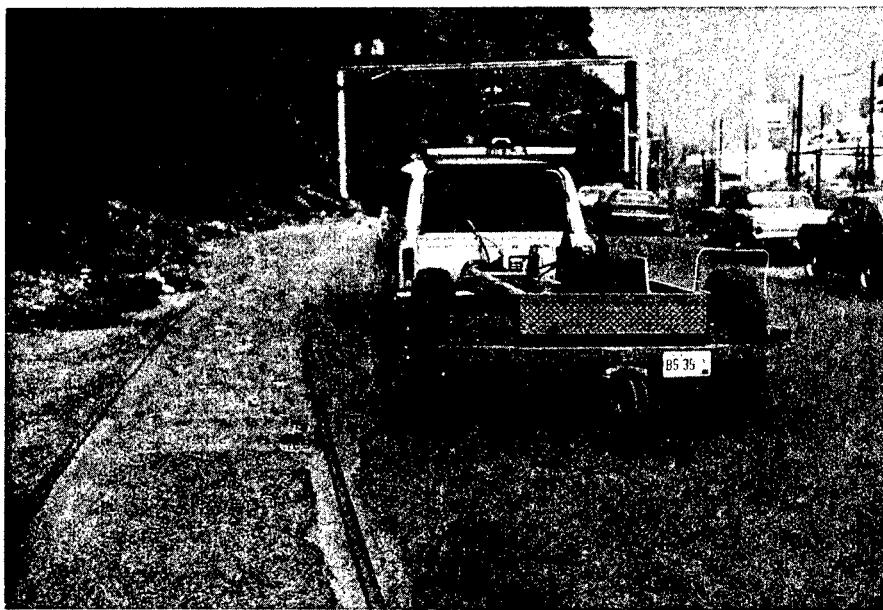

FIGURE 1. GENERAL VIEW OF TEST APPARATUS

FIGURE 2. TIRES UNDERGOING TEST ON DRY PAVEMENT
AT LARGE TOE-IN ANGLE

which measured the forces normal to the wheel plane resulting from this yaw motion (see figure 3). Removable dead weights were employed to vary the test loads. Attached to the rear of the trailer was a "beta-wheel" which measured the yaw angle of the trailer with respect to its forward motion. This yaw angle may have been due to a "crown" on the road surface or high toe in/out angles when the tire cornering forces have "peaked" creating an unstable condition. A watering system, which directed water from the towing vehicle to the front of the test tires allowed testing under either wet or dry road conditions.

To measure braking traction, the trailer was supplied with air-actuated brakes. The same balance which measured the normal forces was also capable of measuring wheel torque. From this torque and the measured loaded radius (spindle height), the braking force could easily be calculated. The test operator controlled the brake mounted on the test wheel. For safety, the vehicle driver had a control which applied both brakes. By carefully regulating the air supply, the test operator could gradually slow down the test wheel until it stopped. The other tire remained free to roll and prevented the trailer from yawing excessively. One tachometer, mounted on the free wheel, measured the forward velocity of the trailer; another measured the speed of the braked wheel. A positive displacement pump, attached to the drive line of the vehicle insured a water layer thickness of 0.02 inches, regardless of test speed.

Ten different tires were tested. To avoid commercial identification they have been designated with the letters A though J. Pictures of their tread patterns are shown in Figures 4 to 13. All tires were 9.00-20. Tire I is the current, standard U. S. Army tire design on a bias ply carcass. Tire H also had a bias carcass. All other tires were of radial construction. All radial tires had a 14PR except tire J, which had a 12PR. The two bias ply tires had 8PR. To observe the influence of ply rating, tires G and J had the same tread pattern. (They may look slightly different in the accompanying photographs because the pictures were taken after the tests on tire J were completed, but before those on tire G had started.)

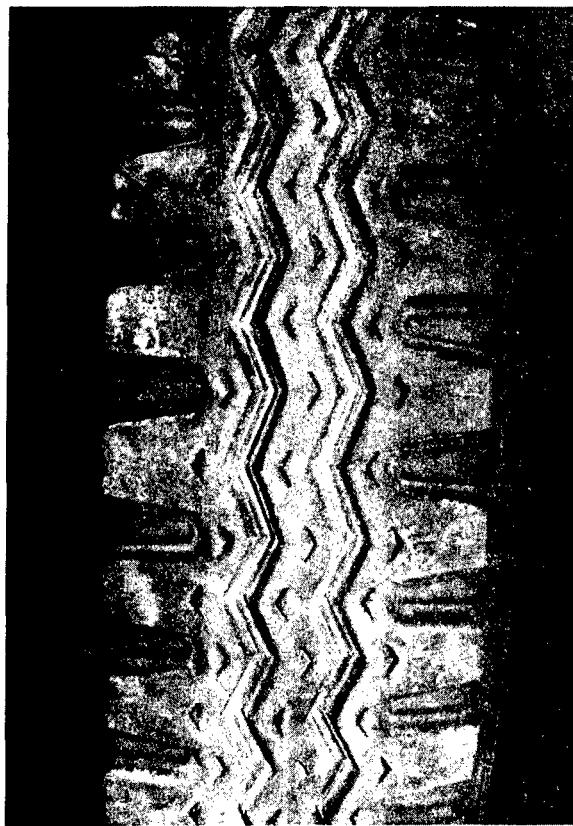

FIGURE 13. TIRE J

All cornering force tests were conducted at 5 mph, at slip angles between plus and minus 10° and at the conditions listed in Table 1.

Table 1
Cornering Force Test Conditions

| <u>Load</u> <u>(lb)</u> | <u>Inflation</u> <u>Pressures</u> <u>(psi)</u> |
|----------------------------|--|
| 3350 | 50, 35 |
| 2168 | 50, 35, 15 |
| 1504 | 50, 35, 15 |

Cornering force tests were conducted under both wet and dry road conditions. Attempts to conduct cornering force tests at the highest load (3350 lb) and lowest pressure (15 psi) yielded erratic results due to the heavily overloaded conditions. They were thus abandoned.

The braking force tests were conducted at the conditions listed in Table 2. All braking tests were conducted wet (0.02 inches of water). Additional tests at other speeds were conducted with the Tire H at 50 psi pressure and both 3350 lb and 2168 lb loads to obtain the relationships between speed and skid number for the road and test conditions employed. Since it is difficult to perform the braking tests at exactly the desired test speed it is necessary to obtain a speed/skid number gradient for the test surface. This gradient (Eq. 3) is then used to correct the actual test data to the nominal speed for comparison purposes.

The road used for all tests was resurfaced in 1972; hence it is considered to be in excellent condition, smooth, with little wear and possessing good traction characteristics. It has an ASTM Skid Number of 55.

Table 2
Braking Force Test Conditions

| <u>Load (1b)</u> | <u>Inflation Pressure (psi)</u> | <u>Nominal Speed (mph)</u> |
|----------------------|---|------------------------------------|
| 3350 | 50 | 30 |
| 2168 | 50 | 30 |
| 2168 | 35 | 20 |
| 2168 | 15 | 10 |
| 1504 | 35 | 20 |
| 1504 | 15 | 10 |

TEST RESULTS

Summaries of all test results are presented in Tables 3 to 12. The loaded radius and tire foot print was recorded for each tire and each load inflation condition.

Data Processing

Braking Force was calculated by Equation (1):

$$BF = \frac{T}{LR} \quad (1)$$

where BF = Braking Force

T = Measured torque at full lock-up (100% skid)

LR = The measured loaded radius (spindle height above level ground) for the load and inflation pressure under study

Skid Number was calculated by Equation (2):

$$SN = \frac{BF}{W - \frac{H}{\ell} BF} \times 100 \quad (2)$$

where SN = Skid Number

BF = Braking force from Equation (1)

| | | | | Ave. | 85.6 | | | | | |

W = Tire Load

H = Trailer Hitch Height

l = Distance from trailer axle to center of hitch

The Adjusted Skid Number was calculated by Equation (3)

$$\text{ASN} = \text{SN} - 1.34 (\text{V}_n - \text{V}_a) \quad (3)$$

where ASN = Adjusted Skid Number

V_n = The Nominal Test Speed (see Table 2)

SN = The calculated Skid Number from Equation (2)

V_a = The measured test speed in mph

1.34 = The correction factor obtained from the additional Tire H tire tests (see above)

The peak braking force was obtained from the torque trace prior to full lock-up. Since this condition is highly unstable, it is not obtained for all test conditions.* The skid conditions for this peak force, calculated by Equation (4), was also recorded

$$S = \frac{\text{V}_a - \text{V}_b}{\text{V}_a} \quad (4)$$

where S = Skid (expressed in per cent)

V_a = The measured test speed

V_b = The measured speed of the braked wheel

All cornering force measurements were plotted against slip angle (see Appendix). The slope of this curve at zero slip angle, zero camber and zero cornering force is called the "cornering coefficient." The cornering forces measured at plus and minus 10°, where the curve has usually reached its peak, were averaged and used as the performance indicator.

*For tires I and G no attempt at all was made to obtain this peak.

The loss in cornering force due to the wet condition at 5 mph was calculated by Equation (5) and is expressed in the tables as per cent.

$$L_5 = 1 - \frac{WCF}{DCF} \quad (5)$$

where L_5 = The loss in cornering force due to wetness
at 5 mph (expressed in per cent)

WCF = The averaged measured cornering force at 10°
slip angle under wet conditions

DCF = The average measured cornering force at 10°
slip angle under dry conditions

It must be noted that these tests are highly dependent on road surface and water film thickness. It is generally accepted that cornering force does not vary with speed in the dry but that speed is significant in the wet. Thus greater differences than those shown in these tables would be exhibited as the forward speed increases.

To compare performance, the cornering force at 10° (Figures 14 to 23) and the Adjusted Skid Numbers (Figures 24 to 33) for each tire were plotted for each condition tested. Straight lines were then drawn between the plotted points as a visual aid for comparison. The figures are presented in descending order of overall performance in the opinion of the authors. (For example, the tire plotted in Figure 14 is deemed superior in cornering characteristics to that in Figure 15; likewise, that in Figure 24 is superior in braking to that in Figure 25). Performance at high load was weighted over that at low load, at high speed over that at low speed; and under wet conditions over that under dry.

From these figures, it appears that the top four tires are Tires G, J, C and D. Tire F appears to be the worst; while the others are somewhere in the middle, some performing better in braking and others better in cornering. Of interest, Tire I, the standard Army NDCC tread performs about equally to Tire H, the NDCC tread with a few added grooves. Likewise, Tires G and J, with the same tread pattern, but different carcasses performed about equally.

CONCLUSIONS

From the data presented, there are no large differences in overall performance between the various tires. There is, however, a gradation between the best and worst tires. Of significance, the effects of rubber compounding, known to be important* are not controlled in this study. With these restrictions we can conclude:

1. The adoption of tread patterns G(or J), C or D will improve on-road braking and cornering performance over the current NDCC pattern (tire I).
2. The differences in performance between the other tires are not significant.

RECOMMENDATIONS

1. Similar tests be conducted in size 7.00-16 (1/4-ton truck size) to determine if similar trends exist at that size and where higher speed tests will not be as dangerous. These higher speeds should show greater differences between wet and dry performance.
2. Analyses be made of performance versus various tread pattern parameters to determine if there is sufficient correlation that can be used in future tread design.
3. If future tests are to be conducted, rubber compound and carcass construction should be identical.
4. Combined braking and turning, which occurs in emergency situations, is worthy of investigation.

* Kelley, J. D. and Albert, B. J., "Tread Design of Tire Affects Wet Traction Most," SAE Journal, September 1968.

ACKNOWLEDGEMENTS

The authors wish to acknowledge the contributions of Mr. Roger Kirk of the U. S. Army Tank-Automotive Command who was the contract technical monitor of this program and provided many valuable suggestions. Also, recognition must be accorded to Mr. I. O. Kamm who supervised the construction of the test trailer and to Mr. Awni Boutros who did the tedious work of taking the raw data from the strip charts and plotted them for our analysis.

Special recognition must be made to the late Mr. C. W. Wilson. Long an active participant in many automotive test programs, the tests conducted here were Bill's final contribution.

| 19. KEY WORDS (Continue on reverse side if necessary and identify by block number) Tire Test, Braking Performance, Cornering Performance, Radial Tire | | |
| 20. ABSTRACT (Continue on reverse side if necessary and identify by block number) Ten sets of tires with nine different off-road tread patterns were tested on a paved surface using a towed, instrumented trailer to measure their cornering characteristics (wet and dry) and their braking performance (wet, full skid). The data obtained and a method for rank ordering is presented. | | |
